Gamma ROS Statistics using Imputed Non-Detects			
GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs			
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)			
For such situations, GROS method may yield incorrect values of UCLs and BTVs			
This is especially true when the sample size is small.			
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Suggested UCL to Use			
95% Student's-t UCL	8441		
When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test			
When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL			
Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.			
Recommendations are based upon data size, data distribution, and skewness.			
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).			
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Gamma ROS Statistics using Imputed Non-Detects			
GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs			
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)			
For such situations, GROS method may yield incorrect values of UCLs and BTVs			
This is especially true when the sample size is small.			
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Gamma ROS Statistics using Imputed Non-Detects			
GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs			
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)			
For such situations, GROS method may yield incorrect values of UCLs and BTVs			
This is especially true when the sample size is small.			
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Nonparametric Distribution Free UCL Statistics

Detected Data appear Approximate Normal Distributed at 5% Significance Level

Suggested UCL to Use

95% KM (t) UCL	636.6		

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test

When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness.

These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs			
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)			
For such situations, GROS method may yield incorrect values of UCLs and BTVs			
This is especially true when the sample size is small.			
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

95% KM (t) UCL	1.377		

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test
When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL
Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).			
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.			
ProUCL computes and outputs H-statistic based UCLs for historical reasons only.			
H-statistic often results in unstable (both high and low) values of UCL95 as shown in examples in the Technical Guide.			
It is therefore recommended to avoid the use of H-statistic based 95% UCLs.			
Use of nonparametric methods are preferred to compute UCL95 for skewed data sets which do not follow a gamma distribution.

Suggested UCL to Use

95% Adjusted Gamma UCL	9016		

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test

When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness.

These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Gamma ROS Statistics using Imputed Non-Detects			
GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs			
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)			
For such situations, GROS method may yield incorrect values of UCLs and BTVs			
This is especially true when the sample size is small.			
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Suggested UCL to Use

95% KM Approximate Gamma UCL	9.862		

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test

When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness.

These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Date/Time of Computation	ProUCL 5.12/18/2019 9:38:20 AM
From File	20190218_rev_GW_ProUCL input.xls
Full Precision	OFF
Confidence Coefficient	95%
Number of Bootstrap Operations	2000

Bis2EthylhexylPhthalate

General Statistics

Total Number of Observations	10	Number of Distinct Observations	5
		Number of Missing Observations	12
Number of Detects	1	Number of Non-Detects	9
Number of Distinct Detects	1	Number of Distinct Non-Detects	4

Warning: Only one distinct data value was detected! ProUCL (or any other software) should not be used on such a data set!

It is suggested to use alternative site specific values determined by the Project Team to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Bis2EthylhexylPhthalate was not processed!

Fluoride

Gamma ROS Statistics using Imputed Non-Detects			
GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs			
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)			
For such situations, GROS method may yield incorrect values of UCLs and BTVs			
This is especially true when the sample size is small.			
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Suggested UCL to Use			
95% KM (t) UCL	0.737		

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness.

These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Naphthalene

General Statistics

Total Number of Observations	10	Number of Distinct Observations	4
		Number of Missing Observations	12
Number of Detects	1	Number of Non-Detects	9
Number of Distinct Detects	1	Number of Distinct Non-Detects	3

Warning: Only one distinct data value was detected! ProUCL (or any other software) should not be used on such a data set!

It is suggested to use alternative site specific values determined by the Project Team to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Naphthalene was not processed!

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs			
This is especially true when the sample size is small.			
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.			
ProUCL computes and outputs H-statistic based UCLs for historical reasons only.			
H-statistic often results in unstable (both high and low) values of UCL95 as shown in examples in the Technical Guide.			
It is therefore recommended to avoid the use of H-statistic based 95% UCLs.			

Use of nonparametric methods are preferred to compute UCL95 for skewed data sets which do not follow a gamma distribution.

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test			
When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL			
Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.			

Recommendations are based upon data size, data distribution, and skewness.

These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Gamma ROS Statistics using Imputed Non-Detects			
GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs			
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)			
For such situations, GROS method may yield incorrect values of UCLs and BTVs			
This is especially true when the sample size is small.			
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Suggested UCL to Use			
95% Student's-t UCL	19203		
When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test			
When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL			
Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.			
Recommendations are based upon data size, data distribution, and skewness.			
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).			
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Gamma ROS Statistics using Imputed Non-Detects			
GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs			
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)			
For such situations, GROS method may yield incorrect values of UCLs and BTVs			
This is especially true when the sample size is small.			
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates			
Minimum	8.084	Mean	144.2

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.			
Recommendations are based upon data size, data distribution, and skewness.			
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).			
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Gamma ROS Statistics using Imputed Non-Detects			
GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs			
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)			
For such situations, GROS method may yield incorrect values of UCLs and BTVs			
This is especially true when the sample size is small.			
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates			
Minimum	0.01	Mean	0.783
Maximum	15.3	Median	0.01

Suggested UCL to Use			
95% H-UCL	2.0562424		
Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.			
Recommendations are based upon data size, data distribution, and skewness.			
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).			
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.			
ProUCL computes and outputs H-statistic based UCLs for historical reasons only.			
H-statistic often results in unstable (both high and low) values of UCL95 as shown in examples in the Technical Guide.			
It is therefore recommended to avoid the use of H-statistic based 95% UCLs.			
Use of nonparametric methods are preferred to compute UCL95 for skewed data sets which do not follow a gamma distribution.

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.			
Recommendations are based upon data size, data distribution, and skewness.			
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).			
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.			
ProUCL computes and outputs H-statistic based UCLs for historical reasons only.			
H-statistic often results in unstable (both high and low) values of UCL95 as shown in examples in the Technical Guide.			
It is therefore recommended to avoid the use of H-statistic based 95% UCLs.			
Use of nonparametric methods are preferred to compute UCL95 for skewed data sets which do not follow a gamma distribution.

Gamma ROS Statistics using Imputed Non-Detects			
GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs			
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)			
For such situations, GROS method may yield incorrect values of UCLs and BTVs			
This is especially true when the sample size is small.			
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Gamma ROS Statistics using Imputed Non-Detects			
GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs			
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)			
For such situations, GROS method may yield incorrect values of UCLs and BTVs			
This is especially true when the sample size is small.			
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Suggested UCL to Use			
95% Chebyshev (Mean, Sd) UCL	32.192562		

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness.

These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Gamma ROS Statistics using Imputed Non-Detects			
GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs			
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)			
For such situations, GROS method may yield incorrect values of UCLs and BTVs			
This is especially true when the sample size is small.			
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test			
When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL			
Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.			
Recommendations are based upon data size, data distribution, and skewness.			
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).			
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Suggested UCL to Use			
95% H-UCL	2.0562424		
Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.			
Recommendations are based upon data size, data distribution, and skewness.			
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).			
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.			
ProUCL computes and outputs H-statistic based UCLs for historical reasons only.			
H-statistic often results in unstable (both high and low) values of UCL95 as shown in examples in the Technical Guide.			
It is therefore recommended to avoid the use of H-statistic based 95% UCLs.			
Use of nonparametric methods are preferred to compute UCL95 for skewed data sets which do not follow a gamma distribution.

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.			
Recommendations are based upon data size, data distribution, and skewness.			
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).			
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.			
ProUCL computes and outputs H-statistic based UCLs for historical reasons only.			
H-statistic often results in unstable (both high and low) values of UCL95 as shown in examples in the Technical Guide.			
It is therefore recommended to avoid the use of H-statistic based 95% UCLs.			
Use of nonparametric methods are preferred to compute UCL95 for skewed data sets which do not follow a gamma distribution.

Gamma ROS Statistics using Imputed Non-Detects			
GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs			
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)			
For such situations, GROS method may yield incorrect values of UCLs and BTVs			
This is especially true when the sample size is small.			
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Suggested UCL to Use			
95% Student's-t UCL	0.5977315		
When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test			
When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL			
Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.			
Recommendations are based upon data size, data distribution, and skewness.			
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).			
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test			
When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL			
Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.			
Recommendations are based upon data size, data distribution, and skewness.			
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).			
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Gamma ROS Statistics using Imputed Non-Detects			
GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs			
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)			
For such situations, GROS method may yield incorrect values of UCLs and BTVs			
This is especially true when the sample size is small.			
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Gamma ROS Statistics using Imputed Non-Detects			
GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs			
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)			
For such situations, GROS method may yield incorrect values of UCLs and BTVs			
This is especially true when the sample size is small.			
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Gamma ROS Statistics using Imputed Non-Detects			
GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs			
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)			
For such situations, GROS method may yield incorrect values of UCLs and BTVs			
This is especially true when the sample size is small.			
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Suggested UCL to Use			
95% H-UCL	21.337328		
Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.			
Recommendations are based upon data size, data distribution, and skewness.			
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).			
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.			
ProUCL computes and outputs H-statistic based UCLs for historical reasons only.			
H-statistic often results in unstable (both high and low) values of UCL95 as shown in examples in the Technical Guide.			
It is therefore recommended to avoid the use of H-statistic based 95% UCLs.			
Use of nonparametric methods are preferred to compute UCL95 for skewed data sets which do not follow a gamma distribution.

Suggested UCL to Use			
95% H-UCL	13.239491		

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness.

These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

ProUCL computes and outputs H-statistic based UCLs for historical reasons only.

H-statistic often results in unstable (both high and low) values of UCL95 as shown in examples in the Technical Guide.

It is therefore recommended to avoid the use of H-statistic based 95% UCLs.

Use of nonparametric methods are preferred to compute UCL95 for skewed data sets which do not follow a gamma distribution.

Gamma ROS Statistics using Imputed Non-Detects			
GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs			
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)			
For such situations, GROS method may yield incorrect values of UCLs and BTVs			
This is especially true when the sample size is small.			
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Suggested UCL to Use			
95% Chebyshev (Mean, Sd) UCL	38.804527		

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness.

These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Mean (detects)	1.2666991		

Gamma ROS Statistics using Imputed Non-Detects			
GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs			
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)			
For such situations, GROS method may yield incorrect values of UCLs and BTVs			
This is especially true when the sample size is small.			
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Gamma ROS Statistics using Imputed Non-Detects			
GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs			
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)			
For such situations, GROS method may yield incorrect values of UCLs and BTVs			
This is especially true when the sample size is small.			
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Gamma ROS Statistics using Imputed Non-Detects			
GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs			
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)			
For such situations, GROS method may yield incorrect values of UCLs and BTVs			
This is especially true when the sample size is small.			
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Gamma ROS Statistics using Imputed Non-Detects			
GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs			
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)			
For such situations, GROS method may yield incorrect values of UCLs and BTVs			
This is especially true when the sample size is small.			
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Gamma ROS Statistics using Imputed Non-Detects			
GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs			
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)			
For such situations, GROS method may yield incorrect values of UCLs and BTVs			
This is especially true when the sample size is small.			
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Gamma ROS Statistics using Imputed Non-Detects			
GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs			
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)			
For such situations, GROS method may yield incorrect values of UCLs and BTVs			
This is especially true when the sample size is small.			
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Gamma ROS Statistics using Imputed Non-Detects			
GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs			
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)			
For such situations, GROS method may yield incorrect values of UCLs and BTVs			
This is especially true when the sample size is small.			
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Detected Data appear Approximate Gamma Distributed at 5% Significance Level			
Suggested UCL to Use			
95% KM Approximate Gamma UCL	1.3155533		
When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test			
When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL			
Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.			
Recommendations are based upon data size, data distribution, and skewness.			
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).			
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Gamma ROS Statistics using Imputed Non-Detects			
GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs			
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)			
For such situations, GROS method may yield incorrect values of UCLs and BTVs			
This is especially true when the sample size is small.			
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

MEMORANDUM

Date: February 28, 2019

To: Mike Cirian, USEPA

From: Laura Jensen, Roux

CC: John Stroiazzo, Glencore
Steve Wright, CFAC
Dick Sloan, MDEQ
Andrew Baris, Roux
Michael Ritorto, Roux
Tom Biksey, EHS Support, LLC

Subject: **Technical Memorandum to Support the Baseline Human Health Risk Assessment at the Columbia Falls Superfund Site**
Former Columbia Falls Aluminum Company Aluminum Reduction Facility
Columbia Falls, Montana

On behalf of Columbia Falls Aluminum Company, LLC (CFAC), Roux Environmental Engineering and Geology, D.P.C. (Roux) and EHS Support, LLC prepared the attached Technical Memorandum to Support the Baseline Human Health Risk Assessment (BHHRA) for the CFAC Superfund Site in Columbia Falls, Montana. This memorandum has been prepared as part of the ongoing Remedial Investigation/Feasibility Study (RI/FS) being conducted pursuant to the Administrative Settlement Agreement and Order on Consent (AOC) dated November 30, 2015 between CFAC and the United States Environmental Protection Agency (USEPA) (CERCLA Docket No. 08-2016-0002).

Should there be any questions or comments on this submission, please do not hesitate to contact me at (631) 230-2300.

Sincerely,

Laura Jensen

Laura Jensen, P.G. (NY)
Senior Hydrogeologist

Re: Technical Memorandum to Support the Baseline Human Health Risk Assessment at the Columbia Falls Superfund Site
Former Columbia Falls Aluminum Company Aluminum Reduction Facility
Columbia Falls, Montana

Introduction

EHS Support, LLC ("EHS Support"), on behalf of Roux Environmental Engineering and Geology D.P.C. (referred to herein as Roux) and Columbia Falls Aluminum Company LLC (CFAC), is providing this Baseline Human Health Risk Assessment (BHHRA) Interim Deliverable as part of the ongoing Remedial Investigation/Feasibility Study (RI/FS) of the Superfund Site referred to as Anaconda Aluminum Co. Columbia Falls Reduction Plant (a/k/a Columbia Falls Aluminum Plant), located in Columbia Falls, Flathead County, Montana (Site; **Figure 1**). The RI/FS is being conducted pursuant to the Administrative Settlement Agreement and Order on Consent dated November 30, 2015, between CFAC and the United States Environmental Protection Agency (USEPA) (Comprehensive Environmental Response, Compensation, and Liability Act [CERCLA] Docket No. 08-2016-0002).

The following BHHRA Interim Deliverable was prepared to supplement the general risk assessment framework provided in the *Baseline Human Health Risk Assessment Work Plan* (BHHRA WP) submitted to USEPA and Montana Department of Environmental Quality (MDEQ) in November 2017, and revised in May 2018 (EHS Support, 2018). The BHHRA Interim Deliverable was submitted to the USEPA on August 30, 2018 and the USEPA provided comments on the Interim Deliverable on November 1, 2018. EHS Support/Roux responded to the comment letter and received verbal approval of responses on February 7, 2019. As specified in the BHHRA WP, this Interim Deliverable provides additional details regarding the overall approach and methodology for the following elements of the BHHRA:

- Selection of chemicals of potential concern (COPCs) in biota

- Calculation of exposure point concentrations (EPCs) for the applicable exposure scenarios, including an example calculation for one COPC per exposure area scenario for both point samples and incremental soil samples
- Risk Assessment Guidance for Superfund (RAGS) Volume I: Part D Table 4 series (i.e., the equations used to calculate uptake of COPCs, as well as the exposure assumptions used for each receptor and exposure pathway)
- RAGS Table 5 and 6 series (i.e., the non-cancer and cancer toxicity data for the COPCs evaluated in the BHHRA)

The following provides the technical approach and references the attached tables compiled for the relevant risk assessment sections that are included in this Interim Deliverable. Further evaluation of the appropriateness of exposure assumptions and model parameters presented in this Interim Deliverable may be warranted in the BHHRA to reduce uncertainty in exposure estimates used to characterize risk to receptors.

Hazard Assessment

Data Used in the Risk Assessment

The environmental data used in the BHHRA were managed in an electronic database and were compiled by constituent, medium, sample location, and sample depth, if applicable. The environmental media data collected within the human health exposure areas defined in the BHHRA Work Plan (**Figure 2**) during the Phase I Site Characterization were included in the BHHRA preliminary database. A final BHHRA database will be based on the data from all phases of site investigation. **Attachment A, Table A-1** through **Table A-12,** present the analytical fluoride data tables for each media by exposure area that is included in the Interim Deliverable.

For groundwater, three exposure areas were defined based on the following datasets:

- Plume Area Upper Hydrogeologic Unit – groundwater wells presented in Appendix 11a
- Western Undeveloped Area Upper Hydrogeologic Unit – groundwater wells presented in Appendix 11b
- Sitewide Below Upper Hydrogeologic Unit – groundwater wells presented in Appendix 11c

Selection of COPCs for Biota

The revised BHHRA Work Plan included a preliminary selection of COPCs in soils, groundwater, surface water, and sediments based upon the results of the Phase I Site Characterization. As discussed in the Work Plan, the selection of COPCs for these media will be finalized based on the evaluation of the combined results of the Phase I and Phase II Site Characterization programs. In addition, the revised BHHRA Work Plan specified that the final selection of COPCs will include the selection of COPCs for ingestion of game and fish; and, that the technical approach for the selection of COPCs in these biotas will be presented in an Interim Deliverable. The technical approach for the selection of COPCs in biota is provided below.

Consistent with the recommendations of the USEPA RSL guidance, the selection of COPCs will be based on a target hazard quotient (THQ) equal to 0.1 to address multiple chemicals that may have non-carcinogenic effects based on the same toxic endpoint and the same mode-of-action, and a target risk equal to 1 x 10^{-6} for carcinogenic effects. To select COPCs for the ingestion of fish exposure pathway, regional screening levels (RSLs) will be calculated using the USEPA RSL Calculator for Ingestion of Fish (USEPA, 2018) for COPCs detected in surface water samples collected in the applicable exposure areas. Consistent with USEPA and MDEQ guidance (MDEQ, 2017) on derivation of water quality standards, an annually normalized fish ingestion rate of 22 grams per day (g/day), or 22,000 milligrams per day (mg/day) will be used in the calculation of screening levels for fish ingestion. A target hazard quotient (THQ) of 0.1 will also be used in the calculation to account for the potential of multiple COPCs with the same toxicological endpoint.

The concentration of a COPC in fish tissue will be determined by applying a bioconcentration factor (BCF) to the maximum surface water concentration using **Equation 1**:

$$C_{fish} = C_{sw} * BCF * CF \qquad \textbf{Equation 1}$$

Where:

- C_{fish} = concentration of COPC in fish (milligrams COPC per kilogram wet weight [mg/kg])
- C_{sw} = concentration of COPC in surface water (micrograms per liter [µ/L])
- BCF = bioconcentration factor (liter per kilogram fish tissue)
- CF = conversion factor (0.001 milligrams per micrograms [mg/µg])

The source of the BCF is the Oak Ridge National Laboratory (ORNL) Risk Assessment Information System (ORNL, 2018).

There currently are no RSLs for the selection of COPCs for the ingestion of the game tissue exposure pathway. Therefore, the residential soil RSLs will be used as a conservative method to select potential COPCs for the exposure of recreational trespasser – hunters – to game tissue affected by Site environmental media.

Exposure Assessment Exposure Point Concentrations

As specified in the revised BHHRA Work Plan, the overall approach and methodology for calculation of the EPCs for the applicable exposure scenarios, including an example calculation for one COPC per exposure area scenario, will be submitted in an Interim Deliverable for USEPA review and comment before completing the BHHRA. In addition, the approach and methodology for calculation of EPCs for Incremental Sampling Methodology (ISM) samples, and an example calculation of one COPC, will be included in the Interim Deliverable. This information is provided below and in **Tables 3-1** through **3-41**. In addition, this section provides the methodology to calculate EPCs for inhalation of fugitive dust by a recreationist/trespasser all-terrain vehicle (ATV) rider; and to calculate EPCs consumption of game tissue by recreationist/trespasser hunters.

As specified in the revised BHHRA WP, the EPC for each environmental media and exposure pathway will be the upper confidence limit (UCL) except as noted differently below. The EPCs will be calculated separately for discrete versus ISM samples for each applicable exposure area. For discrete samples, the

95 percent UCL of the arithmetic mean will be calculated using ProUCL Version 5.1 that was developed for the USEPA (2016) and will be dependent on the distribution of the data. Consistent with the Interstate Technology and Regulatory Council (ITRC) (2012), UCL_{mean} concentrations to estimate EPCs for ISM multiple decision units will be calculated using the Chebyshev UCL or Student's t UCL methods. If the 95 percent UCL of the arithmetic mean exceeds the maximum detected concentration of a COPC, the recommendation provided by the ProUCL software and guidance will be used to develop the EPC. In addition, if a sufficient number of data points (i.e., 10 or greater) are not available for the exposure scenario, the maximum detected concentration will be selected as the EPC if ProUCL software and guidance does not provide a recommendation. Recommendations provided by the ProUCL software for the evaluation of sample results qualified as below the detection level (non-detect) will be followed.

The EPCs for fluoride as the example COPC for each exposure media and receptor were calculated based upon the technical approach outlined above. **Attachment A, Table A-1** through **Table A-12,** presents the analytical fluoride data tables for each media by exposure area that was imported into ProUCL for use in the calculations of the EPCs. The ProUCL outputs are included in **Attachment B**. **Table 3-1** through **Table 3-41** present the calculated EPCs for one example COPC (fluoride) for each exposure media and receptor.

Equation 1 was used to calculate an EPC for fish tissue; however, the BCF was applied to the 95 percent UCL of the arithmetic mean of surface water data rather than the maximum concentration used for selection of COPCs.

The method for calculation of the EPC for fugitive dust generation and game tissue are provided below.

Fugitive Dust Generation

The calculation of an EPC for inhalation of fugitive dust while riding an ATV requires that a particulate emission factor (PEF) be estimated that describes the amount of respirable dust that is in the air. The amount of dust generated is dependent on a number of factors including speed, type and weight of the vehicle, and the type of soil. The PEFs used in the BHHRA were recommended by the USEPA from an ATV activity-based sampling (ABS) study at the Nelson Tunnel Superfund Site in Colorado that were representative of a mountain west soil condition. The ATV ABS study generated three chemical-specific PEF values:

- arsenic – 6.7×10^{-6} kg/m^3 ($1.49 \times 10^{+5}$ m^3/kg)
- lead – 8.5×10^{-6} kg/m^3 ($1.18 \times 10^{+5}$ m^3/kg)
- manganese – 5.2×10^{-6} kg/m^3 ($1.92 \times 10^{+5}$ m^3/kg)

As a conservative measure, for chemicals without a specific ATV ABS PEF, the largest PEF of the three chemical-specific PEFs generated through the Nelson Tunnel study was used.

The analytical data used to develop the EPC included sampling locations located in the Western Undeveloped Area and North-Central Undeveloped Area where recreational trespasser-ATV use observations (i.e., ATV trails) were noted (CFAC personal communication) (**Figure 2**), and the Central Landfill area that did not have ATV observations, but where ATV use is assumed. The 95 percent UCL of the arithmetic mean of the soil concentrations within the three areas were used for the EPCs for fugitive dust exposure because of the limited soil data, limited sampling locations along the observed trails in

the Western Undeveloped Area and North-Central Undeveloped Area, the lack of an observed trail in the Central Landfill area, and the assumption that ATVs will stray from the established ATV trails,. The calculation of an EPC for the recreational trespasser-ATV for the three exposure areas with ATV usage on the Site included the summation of the EPCs for each exposure area weighted by the area of the exposure area. **Table 3-33** provides an example calculation of the EPC with fluoride as the example COPC.

Game Tissue

The white-tailed deer was used as the example game species to estimate the EPC for a recreationist trespasser-hunter. Data specific to deer to estimate COPC concentrations in venison were not identified in the literature, but the following assumptions were used to estimate an EPC for the hunter exposure pathway:

- Deer are ruminants and, as such, are not unlike cattle; thus, it is reasonable to assume they may have similar physiological processes that could yield similar biotransfer factors. Unlike beef, however, deer meat does not undergo marbling with fat, and deer fat is quite unpalatable and likely to be trimmed rather than consumed. Therefore, the biotransfer factors for edible venison are derived by adjusting biotransfer factors for beef to account for differences in the fat content of table-ready beef. Based on data in the United States Department of Agriculture's (USDA) Food Composition Databases (USDA, 2018), a representative value for the lipid content of a strip steak was 14.6 percent, compared with 2.2 percent for ground venison (USDA, 2018).
- Transfer of COPC concentration from soil is considered; although other complete pathways may contribute to the total tissue concentration of a given contaminant in the deer (e.g., ingestion of surface water), they are likely to be negligible compared with the contributions from soil pathways.
- Bioavailability of the contaminant in soil is assumed to be 100 percent. However, estimates of site-specific bioavailability may be incorporated in the refined exposure evaluation in the BHHRA to address the potential uncertainty associated with the magnitude of exposure.

To reflect the assumptions previously noted, venison biotransfer factors were estimated by multiplying beef biotransfer factors by 2.2/14.6 (or 0.2, rounded). Thus:

$$Bv = 0.2(Bb) \qquad \textbf{Equation 2}$$

Where:

- Bv = biotransfer factor for venison (Days per kilogram tissue wet weight [D/kg tissue WW])
- 0.2 = factor to reflect differences in fat content between beef and venison (0.2, unitless, see above)
- Bb = biotransfer factor for beef (D/kg tissue WW)

For organic compounds, biotransfer to beef factors may be estimated using the following model by Research Triangle Institute (RTI) (2005) and recommended by USEPA (2005):

$$Log\ Bb = -0.099\ x \log(Kow)^2 + 1.07\ x \log(Kow) - 3.56 \qquad \textbf{Equation 3}$$

Where:

- Bb = biotransfer factor for beef (D/kg tissue WW, calculated)
- K_{ow} = octanol/water partition coefficient (unitless)

Equation 3 is appropriate for organic chemicals lacking empirical biotransfer data and having a log K_{ow} below 8.2.

Values for inorganic Bb values will be obtained from ingestion-to-beef parameters presented in Baes et al. (1984) or IAEA (1994), which are representative of the fraction of the daily elemental intake in feed that is transferred and remains in a kilogram of beef until slaughter. The Bb value for fluoride (fluorine) in this reference is 0.15 D/kg tissue WW (Baes et al., 1984).

Deer are assumed to be exposed to COPCs by ingesting browse growing on affected soil. It is estimated that deer consume approximately 1.74 kg of browse per day (Sample and Suter, 1994), which is approximately 50 percent dry matter (DM), or 0.87 kg browse DM per day (Mautz et al., 1976). The COPC concentration in browse is estimated from **Equation 4**, which was originally developed for estimating the contaminant concentration in forage to which cattle may be exposed (USEPA, 1994):

$$Cp = (Cs)(BAFplant) \qquad \textbf{Equation 4}$$

Where:

- Cp = concentration of contaminant in (plant) forage (mg/kg plant tissue dry weight [DW], calculated)
- Cs = concentration of contaminant in soil (mg/kg soil DW)
- BAFplant = soil-to-plant biotransfer factor (mg/kg plant DW per mg/kg soil DW, simplified to kg soil/kg plant)

The soil-to-plant bioaccumulation factors obtained from the literature and used to estimate plant tissue COPC concentrations was used for the BAFplant input variable in the venison model. BAFplant values for some inorganic COPCs will be obtained from Baes et al. (1984), which presents plant uptake factors for elemental constituents in both vegetative and reproductive portions of the plant. Because deer browse year-round, and the vegetative parts are more available for the greater part of the year, BAFplant values for the vegetative parts will be used. The use of the vegetative BAFplant is because the translocation of nutrients and elements tends to be greater to the vegetative portion of plants. The vegetative BAFplant for fluoride (fluorine) as presented in Baes et al. (1984) is 0.06.

The concentration of a COPC in venison can be estimated from **Equation 5** (adapted from USEPA [1994]), which includes contributions from both ingestion of browse and incidental soil ingestion by the deer. The soil ingestion rate for deer is assumed to be equal to two percent of its diet (Beyer et al., 1994):

$$Cv = [(FIRbrowse)(Cp)(Bv) + (SIR)(Cs)(Bv)] \qquad \textbf{Equation 5}$$

Where:

- Cv = contamination concentration in venison (mg/kg WW, calculated)
- FIRbrowse = browse ingestion rate (0.87 kg DW/day)

- Cp = contamination concentration in browse DW (mg/kg)
- Bv = biotransfer factor for venison (D/kg tissue WW)
- SIR = soil ingestion rate (estimated as 2 percent of the browse ingestion rate)
- Cs = concentration in soil (mg/kg soil DW)

An area use factor (AUF) was used as an additional adjustment in the calculation of the EPC concentration in venison. As opposed to cattle, which forage in a single location or area, deer are wide-ranging species that may only be exposed to soil in the affected Site for a fraction of their daily activities. The AUF is simply a ratio of the size of the Site to the size of a deer's home range. The home range of a deer is assumed to be the upper bound of the foraging range presented in Sample and Suter (1994). The example includes a hypothetical deer foraging randomly with the terrestrial exposure areas of the CFAC facility (excluding Flathead River and the Backwater Seep Sampling Area). The AUF-adjusted COPC tissue concentrations are used to calculate the Site-wide venison concentration based on the (spatially weighted) deer tissue concentrations at each individual exposure area. The spatial weighting was based on Geographic Information System (GIS) aerial mapping of the Site exposure areas versus Site vegetative habitat and was adjusted to take into account portions of the facility that do not support foraging habitat for the deer. For example, the spatial footprint of a paved parking lot would be excluded from the AUF calculations, and any soil samples from that area may be excluded from the soil exposure point concentration for the venison model, due to the lack of vegetation for browsing. **Table C-1** (**Attachment C**) presents the venison COPC uptake model and AUF EPC for assessing the hunter exposure scenario. Seasonal use may also be considered in the calculation of the AUF to estimate the exposure duration for receptors that may only be present seasonally at the Site. Seasonal use will initially be assumed to be 100 percent; however, estimates of seasonal use may be incorporated into the AUF for the refined exposure evaluation in the BHHRA to address the potential uncertainty associated with the duration of exposure for seasonal receptors at the Site.

Fish Tissue

A typical fish meal is assumed to be 8 ounces per day of uncooked fish, which is measured as wet weight (i.e., as calculated in **Equation 1**). To address intake rates based on what individuals actually consumed, USEPA (2011) estimated net cooking loss for various foods (see Table 13-69; USEPA 2011) based on dripping and volatile losses during cooking, and losses from cutting, shrinkage, excess fat, bones, scraps, and juices. The equation used to convert the C_{fish} intake rate to reflect actual consumption will be added to the exposure tables.

The following is the equation to convert the C_{fish} intake rate (see Equation. 13-3; USEPA 2011):

$$IA = 1 \times (1 - L1) \times (1 - L2) \qquad \textbf{Equation 6}$$

where:

- IA = the adjusted intake rate
- I = the wet weight intake rate
- L1 = the cooking or preparation loss (31.5 percent; USEPA 2011)
- L2 = the post-cooking loss (10.5 percent; USEPA 2011).

Exposure Equations and Assumptions

The equations that will be used to calculate uptake of COPCs, as well as the RME-based exposure assumptions for each receptor and exposure pathway, are presented in **Table 4-1** through **Table 4-6**. Site-specific exposure assumptions for the workers (i.e., industrial, stormwater, and construction), recreationists (i.e., boater, floater, hunter, ATV rider, and fisher), and trespasser will be used in place of default exposure assumptions. Where applicable (i.e., selected COPCs that are mutagenic), the equations from the USEPA (2018) RSL guidance document (e.g. See Section 4.1.1.4 for residential soil equations, USEPA 2018) will be used to address COPCs with a mutagenic mode of action. The equations used will be presented in the BHHRA with the other exposure equations. In addition, where applicable, the time-weighted average calculation methodology will be added for receptors with risk summed for the cancer risk methodology.

The site-specific assumptions are based on factors such as type of recreation anticipated (e.g., hunting, fishing, boating, floating), Site features (e.g., accessibility, vegetation), security measures (e.g., posted) in place, and proximity to residential properties. These exposure assumptions are representative of an RME scenario. In addition, the MDEQ has determined that there was no location in Montana for which climate data were available that did not have a minimum of 4 months of an average snow depth with at least 2 inches, or an average temperature at or below freezing, or both (MDEQ, 2016). However, MDEQ calculated the exposure frequencies using 75 percent of the typical exposure frequency (e.g., for residents, 75 percent of 365 days equaled 270 days of exposure to soils). Therefore, this same conservative exposure frequency assumption (i.e., 75 percent) for surface soil and dust exposure (ingestion, dermal, and inhalation) was used. Other exposure assumptions (e.g., body weight, skin surface area) are based upon the type of receptor and use and were provided in the default guidance documents referenced in the BHHRA Work Plan and listed in the reference section herein. The Montana Fish, Wildlife, and Parks website (e.g., Hunter access guide https://myfwp.mt.gov/fwpPub/hunterAccessGuide) was searched for site-specific information on hunting and fishing seasons, recreational fish and game species, breeding and foraging habitat requirements, creel and bag limits, harvest reports, and distribution and population statistics. Interviews were also conducted with the following individuals:

- Steve Wright, Health and Safety Coordinator, Columbia Falls Aluminum Company LLC – Mr. Wright provided observational information on the activities of recreational trespassers that engage in hunting and ATV riding.
- Rich Birdsell, Owner of Northern Rockies Outfitters, Kalispell, Montana – Mr. Birdsell provided local knowledge regarding recreational and fishing use of the Flathead River near the CFAC Site.
- Kristy Personett, Montana Fish, Wildlife, and Parks, Region 1 – Ms. Personett manages CFAC's Block Management Program (BMP) that provides managed hunting on their land south of the Flathead River; she provided local information on hunting in this area.

The following presents a discussion on Site-specific exposure assumptions that will be used in the BHHRA:

- A stormwater management worker is anticipated to conduct an inspection of the North Percolation Pond and Central Landfill areas once per week for approximately 1 hour per inspection (Steve Wright, personal communication). Consistent with the MDEQ exposure frequency surface soil recommendations, the stormwater management worker is assumed to be exposed to soils 8 months of the year or 38 weeks; therefore, the exposure frequency is 38 days

per year for this receptor. The same exposure frequency is assumed for surface water and sediment.

- The reasonable maximum exposure for the recreationist (i.e., boater and floater) receptor is an exposure frequency of 10 days per year for 1 hour per lunch visit to the Backwater Seep Sampling Area (Rich Birdsell, personal communication). An adolescent recreationist is considered to be 6 to 16 years old; therefore, the exposure duration for the adolescent recreationist is 10 years. An exposure duration of 20 years is assumed for the adult recreationist. For the purposes of dermal exposure, the surface area is assumed to be whole body and is based on USEPA defaults for the adolescent and adult floaters and the exposure time is assumed to be 1 hour per visit.
- The fisher has an estimated exposure frequency of 10 days per year for 20 years and an exposure time of 1 hour per lunch visit to the Backwater Seep Sampling Area (Rich Birdsell, personal communication). Additionally, a fisher is conservatively assumed to keep 2 fish per day of fishing to consume that corresponds to 2 fish meals. A typical meal is assumed to be 8 ounces per day, or 227 grams per day of fish. Therefore, the fish ingestion rate, normalized for one year, of 12,971 milligrams per day is assumed for this receptor.
- Because of the migratory nature of the fish caught by the fisher, and the lack of spawning areas along the reach of the Flathead River adjacent to the Site, the fish are not expected to be exposed to the surface waters within the Backwater Seep Sampling Area except for incidental incursions (Rich Birdsell, personal communication). Therefore, a migration ratio (MR) of 10 percent was applied to the relative percentage of time the fish would be exposed to COPCs within the Backwater Seep Sampling Area. This is a conservative migration ratio given the small surface water habitat within the Backwater Seep Sampling Area and the migratory nature of the fish species.
- The trespasser is an adolescent from 6 to 16 years of age and is assumed to access the Site 7 days per year (Steve Wright, personal communication).
- The recreationist trespasser – hunter is assumed to access the Site 14 days per hunting season (Rich Birdsell, personal communication); for deer, the hunting season is September through November, and one deer is bagged for home consumption. The average weight of dressed deer is approximately 63 kg (average buck and doe, MDEQ website), and approximately 50 percent is edible venison. Therefore, the venison ingestion rate, normalized for one year, is 0.086 kg/day.
- The recreationist trespasser – ATV rider is assumed to access the Site two days per month (Steve Wright, personal communication).

The PEF for the industrial worker, stormwater management worker, hunter, floater, fisher, resident, and trespasser have the same PEF ($1.36 \times 10^{+9}$ m^3/kg). The level of surficial soil disturbance and dust releases for the latter receptor is expected to be greater for the construction worker. Therefore, a construction worker specific PEF for unpaved road traffic of $1.3 \times 10^{+6}$ m^3/kg was calculated using the default assumptions from USEPA (2002) of 20 cars (2 tons/car) and 10 trucks (20 tons/truck), a site-specific number of days with at least 0.01 inches of rainfall (USEPA Exhibit 5-2) of 120, and the remaining default exposure assumptions in the USEPA RSL calculator (November, 2018). The ATV ABS PEF discussed above, and the other chemical-specific properties will be presented in **Table 4-7**; the data for fluoride is included as an example.

Toxicological Assessment

Table 5-1 and **Table 5-2** present the reference doses (RfDs) and reference concentrations (RfCs) selected for all the COPCs that were initially selected in the BHRRA Work Plan, and their target organs. **Table 6-1** and **Table 6-2** present the cancer slope factors (CSFs) and unit risk factors (URFs) for all the COPCs that were initially selected in the BHRRA Work Plan. These tables also include the toxicological data references. The tables will be updated to reflect additional COPCs, if any, based upon the re-screening of the entire RI data set following the completion of Phase II Site Characterization.

Footnotes:
-- = not applicable
- = Result is biased low
+ = Result is biased high
ft = feet
ft-bgs = feet below ground surface
J = The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample.
mg/kg = milligram(s) per kilogram
UJ = The analyte was not deemed above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample.

79					95% H-UCL	102.8						
80												
81	Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.											
82	Recommendations are based upon data size, data distribution, and skewness.											
83	These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).											
84	However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.											
85												
86	ProUCL computes and outputs H-statistic based UCLs for historical reasons only.											
87	H-statistic often results in unstable (both high and low) values of UCL95 as shown in examples in the Technical Guide.											
88	It is therefore recommended to avoid the use of H-statistic based 95% UCLs.											
89	Use of nonparametric methods are preferred to compute UCL95 for skewed data sets which do not follow a gamma distribution.

52	**Gamma ROS Statistics using Imputed Non-Detects**											
53	GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs											
54	GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)											
55	For such situations, GROS method may yield incorrect values of UCLs and BTVs											
56	This is especially true when the sample size is small.											
57	For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

80												
81	Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.											
82	Recommendations are based upon data size, data distribution, and skewness.											
83	These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).											
84	However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.											
85												
86	ProUCL computes and outputs H-statistic based UCLs for historical reasons only.											
87	H-statistic often results in unstable (both high and low) values of UCL95 as shown in examples in the Technical Guide.											
88	It is therefore recommended to avoid the use of H-statistic based 95% UCLs.											
89	Use of nonparametric methods are preferred to compute UCL95 for skewed data sets which do not follow a gamma distribution.

Notes:

C_s = concentration in soil (mg/kg dry weight)

B_b = biotransfer factor for beef (d/kg tissue wet weight)

AUF = aereal ratio of exposure area to receptor foraging range (unitless)

B_v = biotransfer factor for venison; Bb adjusted to Bv multiplying Bb by 0.2 based on the ratio of % fatvenison/% fatbeef (2.9 / 14.4 = 0.2)

BAF_{plant} = soil-to-plant forage bioaccumulation factor (kg soil dry weight / kg plant forage tissue dry weight)

C_p = Concentration in plant forage tissue (mg/kg plant dry weight)

FIR_{browse} = browse ingestion rate (kg dry plant tissue/day)

C_v = concentration in venison tissue (mg/kg venison wet weight)

f_{SI} = Fraction of FIR_{browse} associated with incidental soil ingestion

Ir_v = ingestion rate of venison (kg venison wet weight/day)

EF = exposure frequency (days/year)

ED = exposure duration (years)

BW = body weight (kg)

AT = averaging time (noncancer) (days)

mg/kg = milligrams per kilogram

mg DM/d = milligrams dry matter per day

kg/d = kilograms per day

d/yr = days per year

yr = year

kg = kilograms

d = days

mg/kg-d = milligrams per kilogram per day

mg/kg ww = milligrams per kilogram wet weight

[a] Soil concentrations based on exposure point concentrations (EPCs) calculated for surface soil (0 - 0.5 ft bgs) for each exposure area. Refer to text for discussion on development of soil EPCs. If soil data not available for an exposure area, the soil concentration set to 0 for the purposes of calculation.

[b] Values presented are the vegetated portions of the exopsure area and Site. See table below for non-vegetated and vegetated areas for each human health exposure area.

Human Health Exposure Area	AOC	Area		
		Non-Vegetated (Acres)	Vegetated (Acres)	Total (Acres)
Main Plant Area	1	140.0	150.2	290.1

Table H-1
Estimated Concentrations in Dietary Items of Terrestrial Receptors
Columbia Falls Aluminum Company
Columbia Falls, Montana

Notes:

a, Plant tissue concentrations (mg/kg dry weight) calculated based on regression models, where ln([tissue]) = B0 + B1(ln[soil]).
Slopes (B1) and intercepts (B0) are as follows:

Analyte	B0	Data Source
Antimony	-3.233	USEPA (2007)
Beryllium	-0.5361	USEPA (2007)
Cadmium	-0.475	Bechtel-Jacobs (1998)
Copper	0.668	Bechtel-Jacobs (1998)
Lead	-1.328	Bechtel-Jacobs (1998)
Mercury	0.544	Bechtel-Jacobs (1998)
Nickel	-2.223	Bechtel-Jacobs (1998)
Selenium	-0.677	Bechtel-Jacobs (1998)
Zinc	1.575	Bechtel-Jacobs (1998)
Acenaphthene	-5.562	USEPA (2007)
Acenaphthylene	-1.144	USEPA (2007)
Anthracene	-0.9887	USEPA (2007)
Benzo(a)anthracene	-2.7078	USEPA (2007)
Benzo(a)pyrene	-2.0615	USEPA (2007)
Benzo(g,h,i)perylene	-0.9313	USEPA (2007)
Benzo(k)fluoranthene	-2.1579	USEPA (2007)
Chrysene	-2.7078	USEPA (2007)
Fluorene	-5.562	USEPA (2007)
Phenanthrene	-0.1665	USEPA (2007)

b, Chromium values used for hexavalent chromium; cyanide value used for free cyanide.

c, Soil-to-plant BAF based on Kow model for non-ionic organic compounds (rinsed foliage data) provided in USEPA (2005), where: log BAF = -0.4057(log Kow) + 1.781;
log Kow values obtained from EPA EpiSuite V. 1.69, KOWWIN module.

d, Soil-invertebrate bioaccumulation factor could not be identified; therefore, a conservative default accumulation factor of 1.0 was assummed.

e, Soil invertebrate tissue concentrations (mg/kg dry weight) calculated based on regression models, where ln([tissue]) = B0 + B1(ln[soil])
and slopes (B1) and intercepts (B0) are as follows:

Analyte	B0	Data Source
Arsenic	-1.421	Sample et al. (1999)
Cadmium	2.114	Sample et al. (1999)
Lead	-0.218	Sample et al. (1999)
Manganese	-0.809	Sample et al. (1999)
Selenium	-0.075	Sample et al. (1999)
Zinc	4.449	Sample et al. (1999)
2,3,7,8-TCDD	3.533	Sample et al. (1998a)

f, Bioaccumulation factor estimated as the product of the soil-plant and ingestion-beef factors reported in Baes et al. (1984)

f, Median soil-to-plant uptake factors reported in Bechtel (1998a) were used as bioaccumulation factors.

g, Small mammal tissue concentrations (mg/kg dry weight) calculated based on regression models, where ln([tissue]) = B0 + B1(ln[soil])
and slopes (B1) and intercepts (B0) are as follows:

Table H-1
Estimated Concentrations in Dietary Items of Terrestrial Receptors
Columbia Falls Aluminum Company
Columbia Falls, Montana

Analyte	B0	Data Source
Arsenic	-4.8471	Sample et al. (1998b)
Cadmium	-1.2571	Sample et al. (1998b)
Chromium	-1.4599	Sample et al. (1998b)
Cobalt	-4.4669	Sample et al. (1998b)
Copper	2.042	Sample et al. (1998b)
Lead	0.0761	Sample et al. (1998b)
Nickel	-0.2462	Sample et al. (1998b)
Selenium	-0.4158	Sample et al. (1998b)
Zinc	4.3632	Sample et al. (1998b)
2,3,7,8-TCDD	0.8113	Sample et al. (1998b)

h, Pentachlorophenol concentration in small mammal tissue (mg/kg dry weight) calculated based on regression models, where [tissue] = 0.198 + 0.00452([dietinvertebrate])

h, USEPA (2005) assumes bioaccumulation of PAHs by birds and mammals is minimal due to rapid metabolism of these compounds after ingestion.

i, Small mammal tissue estimated based on the medial BAF for the general model presented in Sample et al. (1998b)

j, No value was identified in the literature. Soil-to-small mammal BF estimated based on the approach presented in Table 5, consistent with LANL (2017).

Table H-2

Notes:

C_s = concentration in soil (mg/kg dry weight)

B_b = biotransfer factor for beef (d/kg tissue wet weight)

AUF = aereal ratio of exposure area to receptor foraging range (unitless)

B_v = biotransfer factor for venison; Bb adjusted to Bv multiplying Bb by 0.2 based on the ratio of % fatvenison/% fatbeef (2.9 / 14.4 = 0.2)

BAF_{plant} = soil-to-plant forage bioaccumulation factor (kg soil dry weight / kg plant forage tissue dry weight)

C_p = Concentration in plant forage tissue (mg/kg plant dry weight)

FIR_{browse} = browse ingestion rate (kg dry plant tissue/day)

C_v = concentration in venison tissue (mg/kg venison wet weight)

f_{SI} = Fraction of FIR_{browse} associated with incidental soil ingestion

Ir_v = ingestion rate of venison (kg venison wet weight/day)

EF = exposure frequency (days/year)

ED = exposure duration (years)

BW = body weight (kg)

AT = averaging time (noncancer) (days)

mg/kg = milligrams per kilogram

mg DM/d = milligrams dry matter per day

kg/d = kilograms per day

d/yr = days per year

yr = year

kg = kilograms

d = days

mg/kg-d = milligrams per kilogram per day

mg/kg ww = milligrams per kilogram wet weight

[a] Soil concentrations based on exposure point concentrations (EPCs) calculated for surface soil (0 - 0.5 ft bgs) for each exposure area. Refer to text for discussion on development of soil EPCs. If soil data not available for an exposure area, the soil concentration set to 0 for the purposes of calculation.

[b] Values presented are the vegetated portions of the exopsure area and Site. See table below for non-vegetated and vegetated areas for each human health exposure area.

Human Health Exposure Area	AOC	Area

Notes:

C_s = concentration in soil (mg/kg dry weight)

B_b = biotransfer factor for beef (d/kg tissue wet weight)

AUF = aereal ratio of exposure area to receptor foraging range (unitless)

B_v = biotransfer factor for venison; Bb adjusted to Bv multiplying Bb by 0.2 based on the ratio of % fatvenison/% fatbeef (2.9 / 14.4 = 0.2)

BAF_{plant} = soil-to-plant forage bioaccumulation factor (kg soil dry weight / kg plant forage tissue dry weight)

C_p = Concentration in plant forage tissue (mg/kg plant dry weight)

FIR_{browse} = browse ingestion rate (kg dry plant tissue/day)

C_v = concentration in venison tissue (mg/kg venison wet weight)

f_{SI} = Fraction of FIR_{browse} associated with incidental soil ingestion

Ir_v = ingestion rate of venison (kg venison wet weight/day)

EF = exposure frequency (days/year)

ED = exposure duration (years)

BW = body weight (kg)

AT = averaging time (noncancer) (days)

mg/kg = milligrams per kilogram

mg DM/d = milligrams dry matter per day

kg/d = kilograms per day

d/yr = days per year

yr = year

kg = kilograms

d = days

mg/kg-d = milligrams per kilogram per day

mg/kg ww = milligrams per kilogram wet weight

[a] Soil concentrations based on exposure point concentrations (EPCs) calculated for surface soil (0 - 0.5 ft bgs) for each exposure area. Refer to text for discussion on development of soil EPCs. If soil data not available for an exposure area, the soil concentration set to 0 for the purposes of calculation.

[b] Values presented are the vegetated portions of the exopsure area and Site. See table below for non-vegetated and vegetated areas for each human health exposure area.

Human Health Exposure Area	AOC	Area

Notes:

C_s = concentration in soil (mg/kg dry weight)

B_b = biotransfer factor for beef (d/kg tissue wet weight)

AUF = aereal ratio of exposure area to receptor foraging range (unitless)

B_v = biotransfer factor for venison; Bb adjusted to Bv multiplying Bb by 0.2 based on the ratio of % fatvenison/% fatbeef (2.9 / 14.4 = 0.2)

BAF_{plant} = soil-to-plant forage bioaccumulation factor (kg soil dry weight / kg plant forage tissue dry weight)

C_p = Concentration in plant forage tissue (mg/kg plant dry weight)

FIR_{browse} = browse ingestion rate (kg dry plant tissue/day)

C_v = concentration in venison tissue (mg/kg venison wet weight)

f_{SI} = Fraction of FIR_{browse} associated with incidental soil ingestion

Ir_v = ingestion rate of venison (kg venison wet weight/day)

EF = exposure frequency (days/year)

ED = exposure duration (years)

BW = body weight (kg)

AT = averaging time (noncancer) (days)

mg/kg = milligrams per kilogram

mg DM/d = milligrams dry matter per day

kg/d = kilograms per day

d/yr = days per year

yr = year

kg = kilograms

d = days

mg/kg-d = milligrams per kilogram per day

mg/kg ww = milligrams per kilogram wet weight

[a] Soil concentrations based on exposure point concentrations (EPCs) calculated for surface soil (0 - 0.5 ft bgs) for each exposure area. Refer to text for discussion on development of soil EPCs.
If soil data not available for an exposure area, the soil concentration set to 0 for the purposes of calculation.

[b] Values presented are the vegetated portions of the exopsure area and Site. See table below for non-vegetated and vegetated areas for each human health exposure area.

Human Health Exposure Area	AOC	Area

Notes:

C_s = concentration in soil (mg/kg dry weight)

B_b = biotransfer factor for beef (d/kg tissue wet weight)

AUF = aereal ratio of exposure area to receptor foraging range (unitless)

B_v = biotransfer factor for venison; Bb adjusted to Bv multiplying Bb by 0.2 based on the ratio of % fatvenison/% fatbeef (2.9 / 14.4 = 0.2)

BAF_{plant} = soil-to-plant forage bioaccumulation factor (kg soil dry weight / kg plant forage tissue dry weight)

C_p = Concentration in plant forage tissue (mg/kg plant dry weight)

FIR_{browse} = browse ingestion rate (kg dry plant tissue/day)

C_v = concentration in venison tissue (mg/kg venison wet weight)

f_{SI} = Fraction of FIR_{browse} associated with incidental soil ingestion

Ir_v = ingestion rate of venison (kg venison wet weight/day)

EF = exposure frequency (days/year)

ED = exposure duration (years)

BW = body weight (kg)

AT = averaging time (noncancer) (days)

mg/kg = milligrams per kilogram

mg DM/d = milligrams dry matter per day

kg/d = kilograms per day

d/yr = days per year

yr = year

kg = kilograms

d = days

mg/kg-d = milligrams per kilogram per day

mg/kg ww = milligrams per kilogram wet weight

[a] Soil concentrations based on exposure point concentrations (EPCs) calculated for surface soil (0 - 0.5 ft bgs) for each exposure area. Refer to text for discussion on development of soil EPCs.
If soil data not available for an exposure area, the soil concentration set to 0 for the purposes of calculation.

[b] Values presented are the vegetated portions of the exopsure area and Site. See table below for non-vegetated and vegetated areas for each human health exposure area.

Human Health Exposure Area	AOC	Area

Appendix K Groundwater Statistical Analysis

Appendix K. Evaluation of Fluoride Concentrations in Groundwater Samples from Aluminum City Neighborhood Residential Wells

On behalf of the Columbia Falls Aluminum Company, LLC (CFAC), Roux Associates, Inc. (Roux) performed a statistical evaluation of fluoride concentrations measured in groundwater samples from Aluminum City water supply wells. Aluminum City is a residential neighborhood located adjacent to the southwest corner of the former CFAC aluminum reduction facility (commonly referred to as an aluminum smelter) located in Flathead County, Montana (Site). The Site is the subject on an ongoing Remedial Investigation/Feasibility Study (RI/FS) that is being conducted pursuant to the Administrative Settlement Agreement and Order on Consent dated November 30, 2015, between CFAC and the United States Environmental Protection Agency (USEPA) (Comprehensive Environmental Response, Compensation, and Liability Act [CERCLA] Docket No. 08-2016-0002).

Analyses of quarterly groundwater samples collected from residential water supply wells in the Aluminum City neighborhood have detected the presence of fluoride, a naturally-occurring substance, in concentrations ranging from below laboratory method detection limits (MDLs) to a maximum of 0.28 mg/L. To determine whether fluoride concentrations in groundwater beneath Aluminum City are related to naturally-occurring conditions or should be attributed to historical Site operations, Aluminum City fluoride data was compared with regional groundwater analytical results (specifically, fluoride concentrations in public water supply [PWS] wells for Flathead County, MT).

Groundwater fluoride data from Flathead County PWS wells collected from 2013 to 2016 were obtained from the Montana Department of Environmental Quality (MDEQ) (Table 1a and Table 1b). The MDEQ confirmed that drinking water sources included in the dataset were not fluoridated.[1] Data from the Aluminum City wells were collected in quarterly sampling events from 2014 through 2017 (Table 2a and Table 2b). In order to properly compare the data, the following data preparation process was performed:

- Temporal averages were calculated for each PWS location and for each Aluminum City well and utilized in the below described statistical analysis (Tables 1b and 2b);
- Fluoride concentrations below laboratory MDLs were included in the analysis as one half the reporting limit (0.5 * MDL);
- Field duplicate samples were not included in the Aluminum City dataset;
- There are four instances in the Aluminum City dataset in which a monitoring well has two results for a given date (GW09 on 11/29/2016, GW12 on 07/14/2016, GW12 on 09/07/2016, and GW23 on 03/08/2017). In these instances, the greater of the two values was retained to be conservative; and
- PWS concentrations were reported in milligrams per liter (mg/L), while Aluminum City data was provided in micrograms per liter (µg/L). Aluminum City data was converted to mg/L for the purposes of these analyses.

Summary statistics for the two processed datasets are detailed in the table below.

Temporal Average Statistics	Unit	PWS dataset	AC dataset
Number of observations	Count	117	17
Minimum	mg/L	0.03	0.05
First Quartile	mg/L	0.08	0.07

[1] Email correspondence with Gregory Butts, Field Services Section Supervisor dated February 5, 2018.

Median	mg/L	0.12	0.10
Third Quartile	mg/L	0.15	0.11
Maximum	mg/L	2.75	0.18
Mean	mg/L	0.17	0.10
Standard Deviation	mg/L	0.29	0.04

To compare the means of groundwater fluoride concentrations between samples collected from PWS in Flathead County, MT and samples collected from residential water supply wells in Aluminum City, two-sample t-tests were performed utilizing ProUCL (version 5.1). The null hypothesis of the one-sided two-sample t-test is that the mean fluoride concentration from the PWS dataset is less than or equal to the mean fluoride concentration from the Aluminum City dataset (H_0: $\mu_1 \leq \mu_2$); and the alternative hypothesis is that the mean fluoride concentration from the PWS dataset is greater than the mean fluoride concentration from the Aluminum City dataset (H_A: $\mu_1 > \mu_2$).

First, an F-test for the equality of two variances was performed. The null hypothesis of the F-test is that the variances of the two datasets are equal (H_0: $\sigma_1 = \sigma_2$). There is sufficient evidence (F-statistic = 61.503 | df = 116,16 | p = 0.000) using a significance level $\alpha = 0.05$ to conclude that the variances between the two datasets are not equal. Due to the unequal sample variances, the pooled sample variance method was not utilized for the t-test and, instead, the Welch-Satterthwaite method for two-sample t-tests was employed (Welch's t-test).

Using the one-sided Welch's t-test, the t-statistic is equal to 2.380 (df = 131.5) with p = 0.009. Because the p-value is less than $\alpha = 0.05$, there is sufficient evidence to reject the null hypothesis and conclude that the mean fluoride concentration from the PWS dataset is greater than the mean fluoride concentration from the Aluminum City dataset.

Following the preliminary analysis, the data was evaluated for outliers. Box plots (Figure 1) and Q-Q plots (Figures 2 and 3) were generated to visually identify potential outliers. Three potential upper-tail outliers were visually identified in the PWS dataset; no potential lower-tail PWS outliers were identified. No potential upper- or lower-tail outliers were visually identified in the Aluminum City dataset. Statistical outlier tests were then performed to confirm the identification of potential outliers. Rosner's outlier test was performed on the PWS dataset for the three suspected outliers, and the three greatest fluoride concentrations were identified as potential outliers at the 5% significance level. These potential outliers correspond with temporal averages at the following locations: Montana Academy in Marion, MT; Kila School District No. 20 in Kalispell, MT; and Wettington Water Inc in Kalispell, MT. MDEQ identified two of these regions (the two locations with the greatest fluoride concentrations) as exhibiting naturally occurring elevated fluoride concentrations.[2] For the AC dataset, Dixon's outlier test was performed and no outliers were identified.

When the F-test is performed excluding these outliers from the dataset, the test once again indicates the variances are not equal (F-statistic = 4.183 | df = 113,16 | p = 0.002 at $\alpha = 0.05$). The one-sided Welch's t-test yields a t-statistic equal to 2.435 (df = 40.0) with p = 0.010 at $\alpha = 0.05$. Because the p-value is less than $\alpha = 0.05$, there is sufficient evidence to reject the null hypothesis and conclude that the mean fluoride concentration from the PWS dataset is greater than the mean fluoride concentration from the Aluminum City dataset.

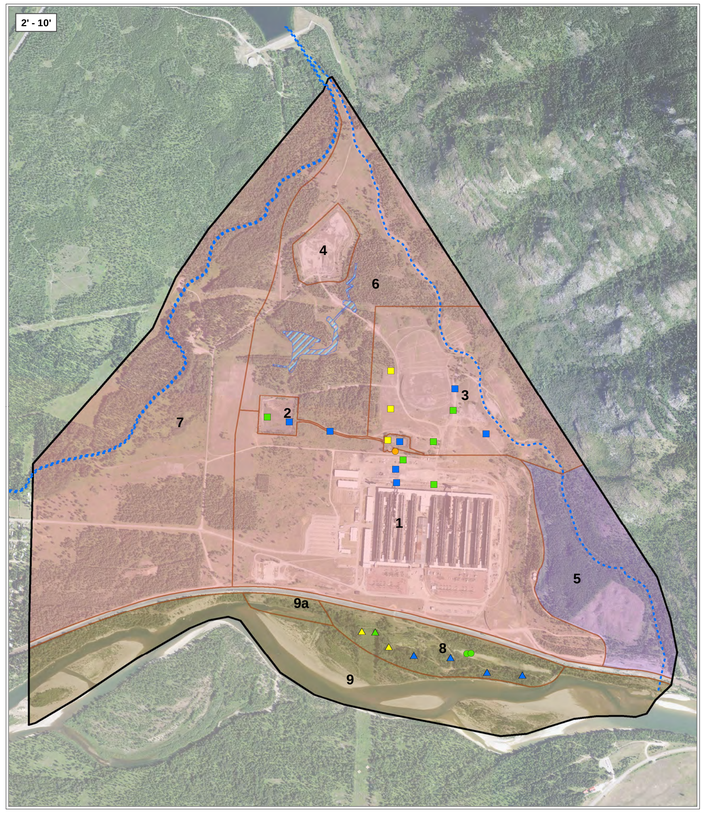
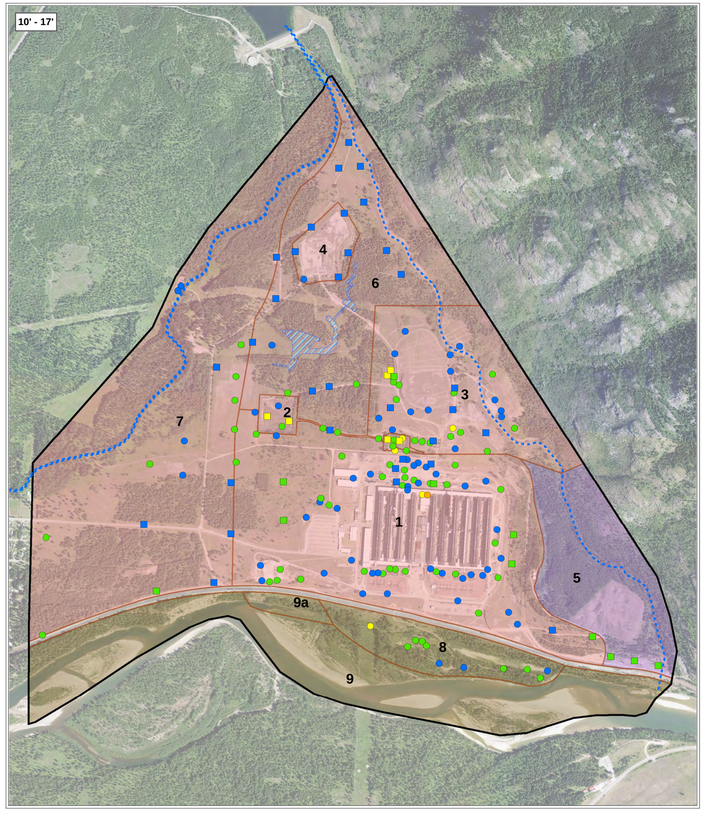
Appendix K. Evaluation of Fluoride Concentrations in Groundwater Samples from Aluminum City Neighborhood Residential Wells



Based on the analyses described herein, Roux Associates is confident in the conclusion that the mean concentration of fluoride in the Aluminum City residential water supply wells is statistically less than the mean concentration of fluoride in other drinking water wells in the region. In addition, hydrogeologic investigations have shown that the flow of groundwater beneath the Site is toward the Flathead River, not towards Aluminum City (see Groundwater/Surface Water Data Summary Report dated March 16, 2018; Roux Associates, 2018). Together, these results provide multiple lines of evidence indicating that fluoride concentrations in groundwater beneath Aluminum City are related to naturally-occurring conditions; not historical operations at the Site.



All ProUCL output is provided in Attachment 1.
